## *Sintering trials results*

# Results about biochar application in sintering process

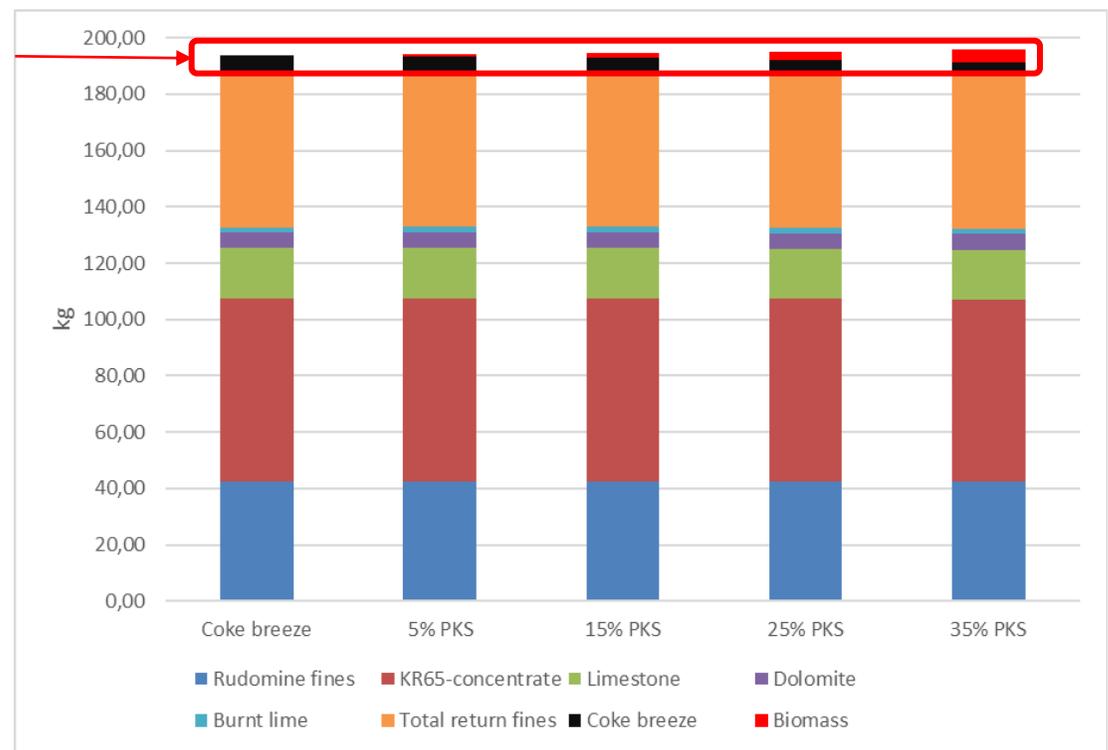

## EXAMPLE OF THE COMPOSITION OF THE SINTERING MIXTURE

### Charcoal

### Raw PKS

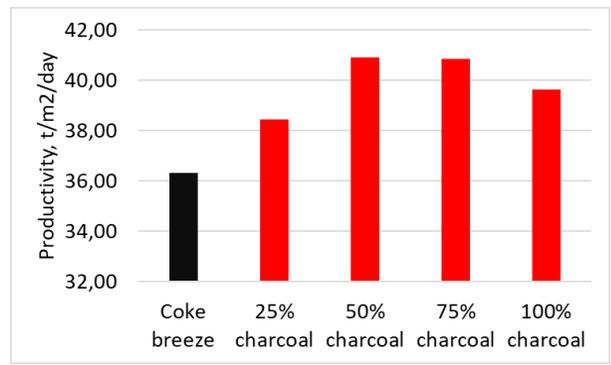

The fuel fraction in the sintering blend is approximately 5%. Complete substitution with charcoal is feasible, whereas PKS can be used up to a maximum of 35% due to its high content of oily components, which increases the risk of system clogging and potential ignition within the gas-cleaning equipment.

# Results about biochar application in sintering process

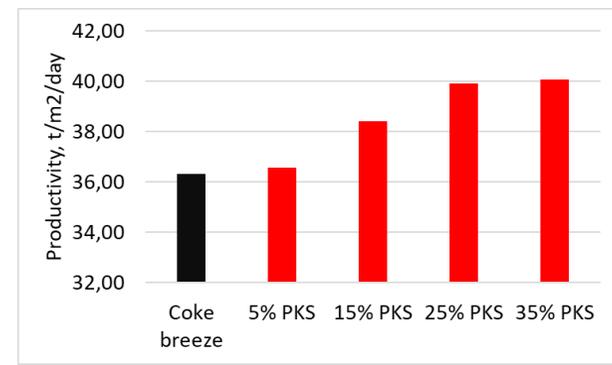

## PRODUCTIVITY

### Charcoal

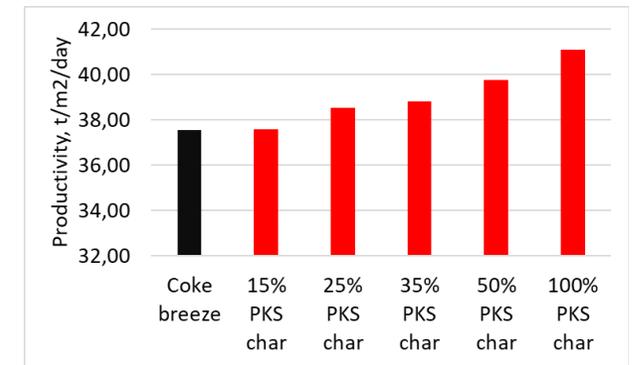

Charcoal substitution increases productivity up to a 50% replacement level; further addition reduces productivity but still maintains values above those of coke breeze

### Raw PKS

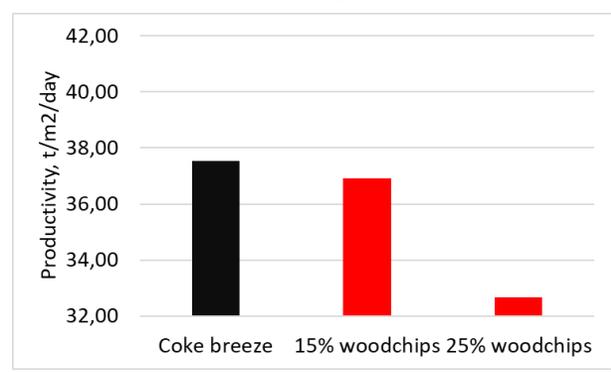

Productivity rises progressively with increasing raw PKS substitution and remains consistently higher than for coke breeze

### PKS char

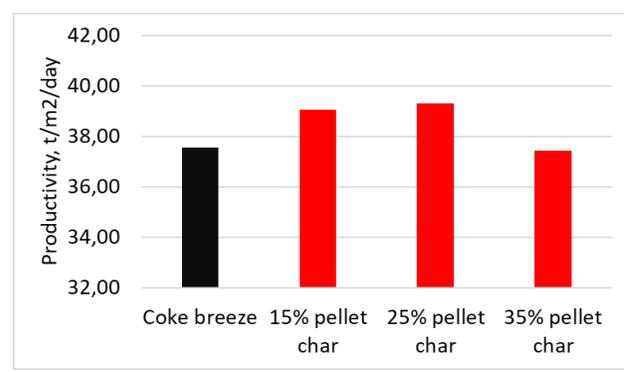

Productivity increases with rising PKS char substitution and remains higher than for coke breeze

### Wood chips char

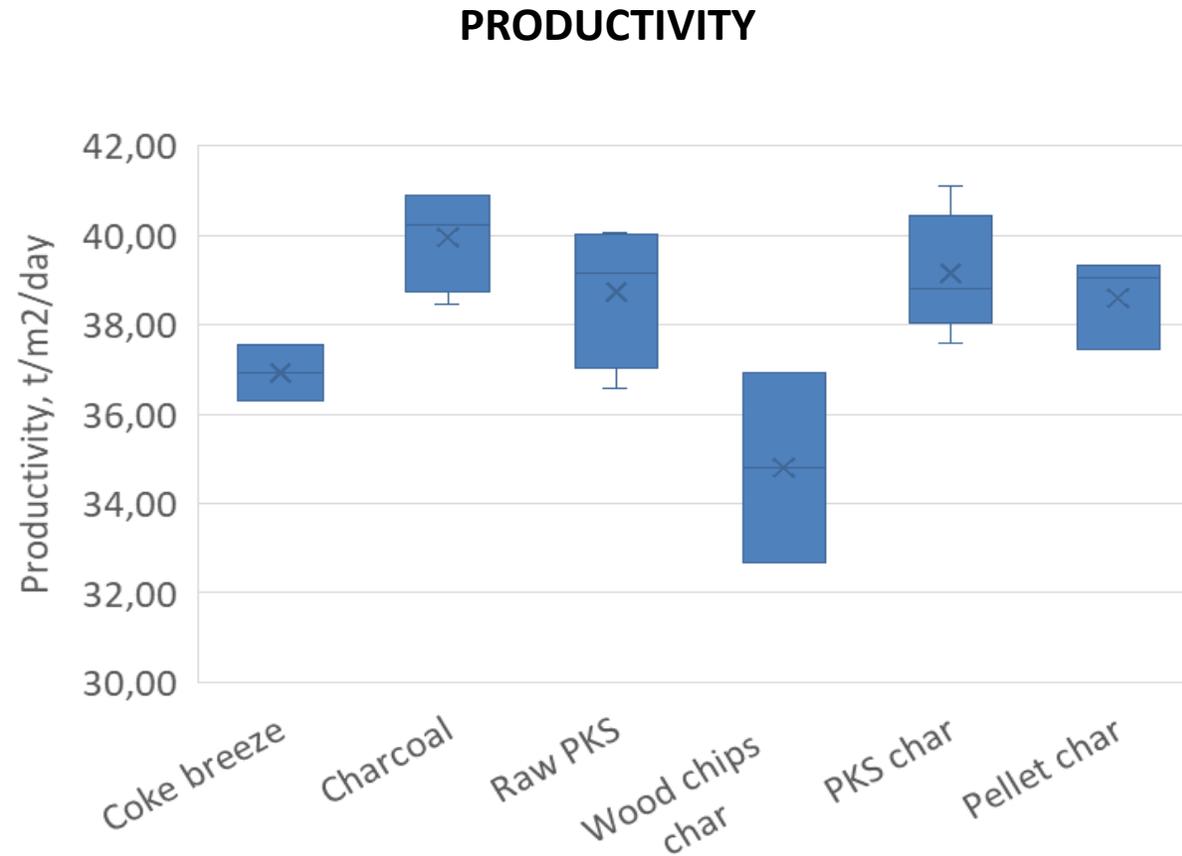

Wood-chips char reduces productivity, yielding values lower than those of coke breeze

### Pellet char

Pellet char enhances productivity up to a 25% substitution level; further replacement decreases productivity

# Results about biochar application in sintering process

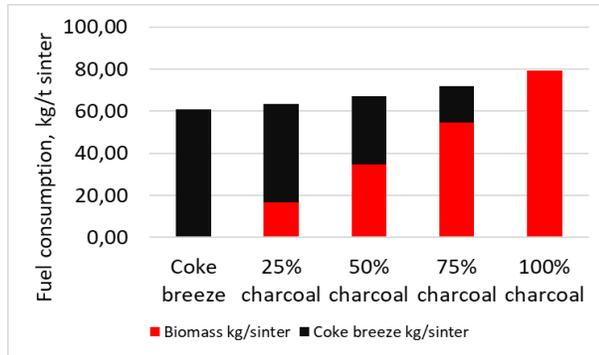

The results show that charcoal, raw PKS, PKS char, and pellet char all yield higher sinter productivity than coke breeze, with charcoal and raw PKS achieving the highest values, whereas wood-chips char is the only substitute exhibiting a pronounced reduction in productivity.

# Results about biochar application in sintering process

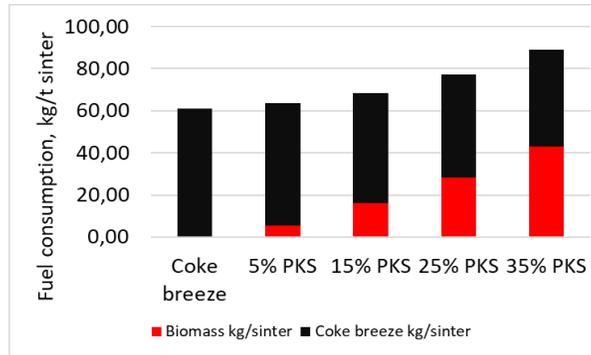

## SOLID FUEL CONSUMPTION

### Charcoal

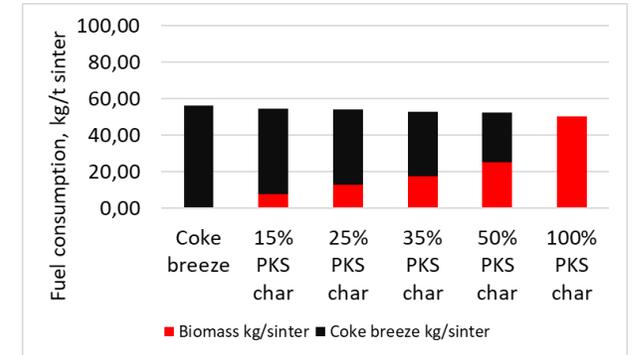

Charcoal substitution increases solid fuel consumption due to its lower carbon content relative to coke breeze, with feasible replacement levels up to 100%

### Raw PKS

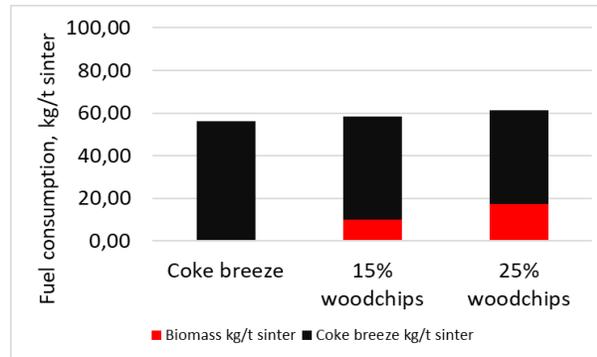

Raw PKS substitution similarly elevates solid fuel consumption because of its reduced carbon content, and its maximum practical replacement ratio is 35%

### PKS char

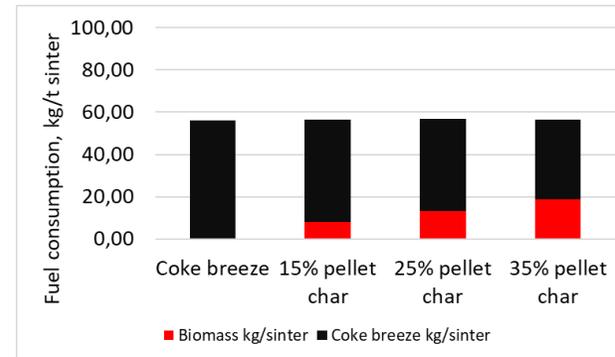

PKS char lowers solid fuel consumption, reflecting its higher carbon concentration, and can be introduced at substitution rates up to 100%

### Wood chips char

Wood-chips char causes a slight increase in solid fuel consumption, with permissible substitution levels reaching about 25%

### Pellet char

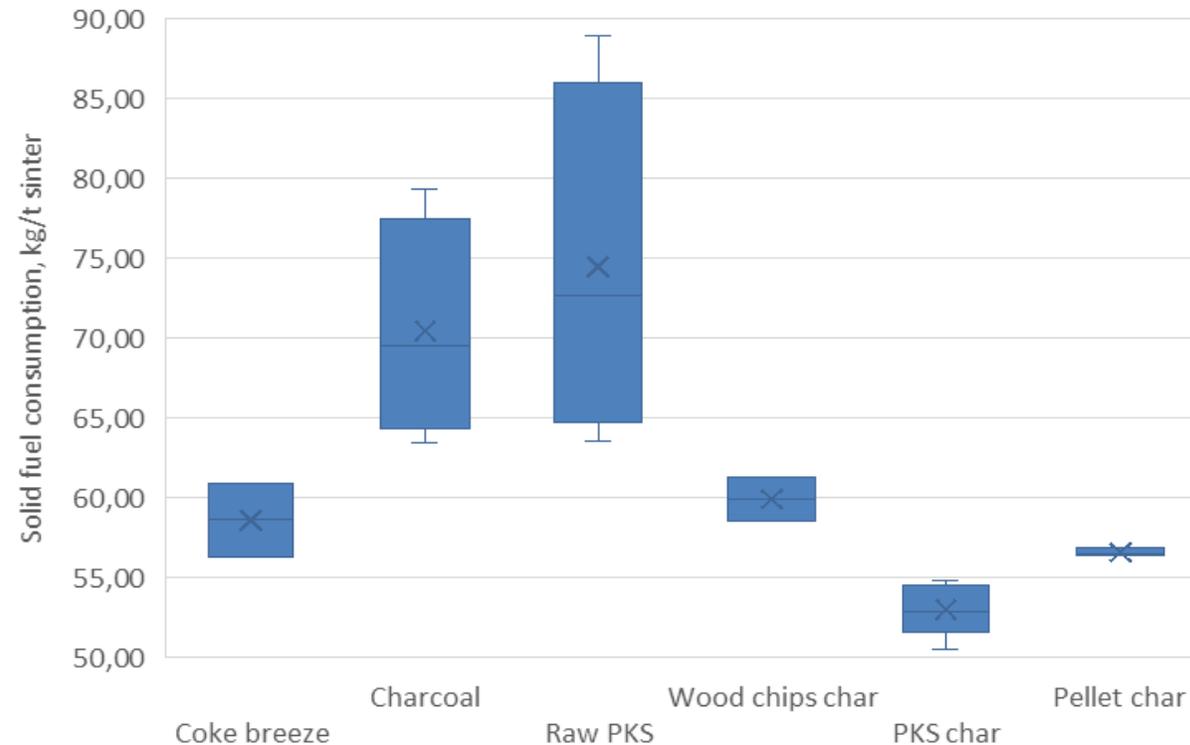

Pellet char slightly reduces solid fuel consumption and can be applied at replacement rates of up to 35%

# Results about biochar application in sintering process

## SOLID FUEL CONSUMPTION

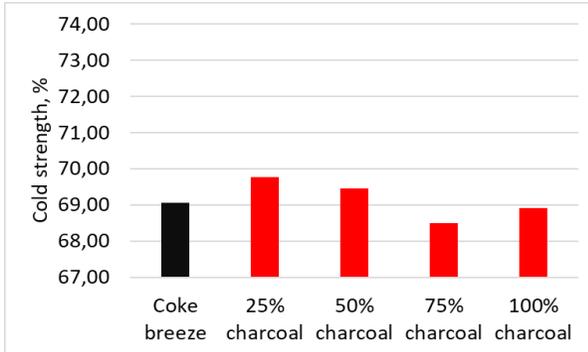

Solid fuel consumption increases markedly when coke breeze is replaced with charcoal or raw PKS, whereas PKS char and pellet char reduce fuel demand below the coke-breeze baseline, with wood-chips char showing only a slight increase.

# Results about biochar application in sintering process

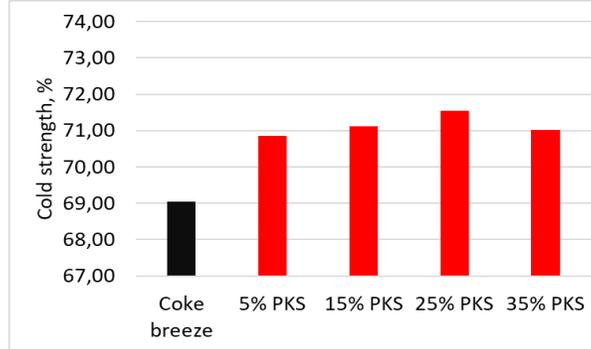

## ISO T COLD STRENGTH

### Charcoal

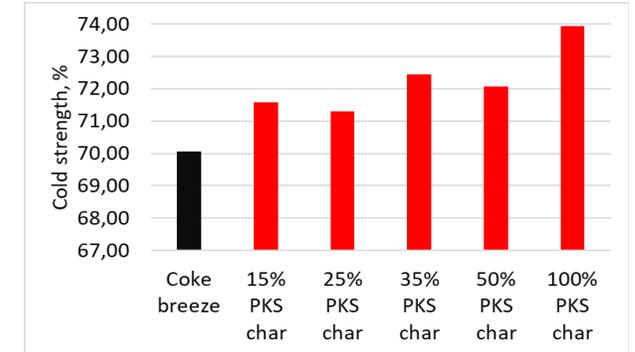

Charcoal substitution increases ISO T up to a 50% replacement level; higher substitution decreases ISO T to values below or similar to those of coke breeze

### Raw PKS

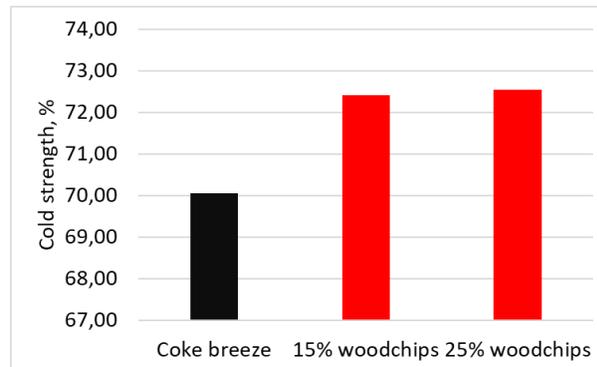

Increasing raw PKS substitution enhances ISO T, yielding strengths consistently above those of coke breeze

### PKS char

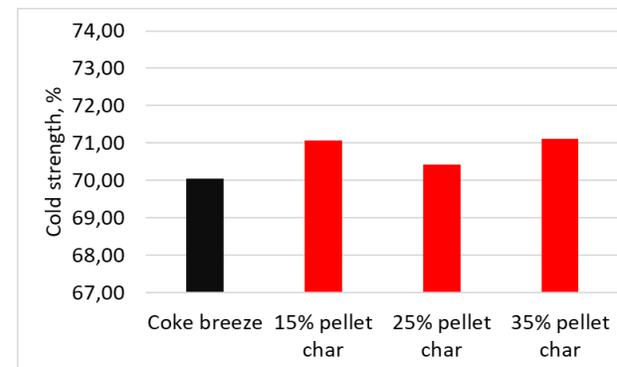

ISO T rises with higher PKS char substitution and remains superior to the coke-breeze benchmark

### Wood chips char

Wood-chips char substitution results in ISO T values exceeding those of coke breeze

### Pellet char

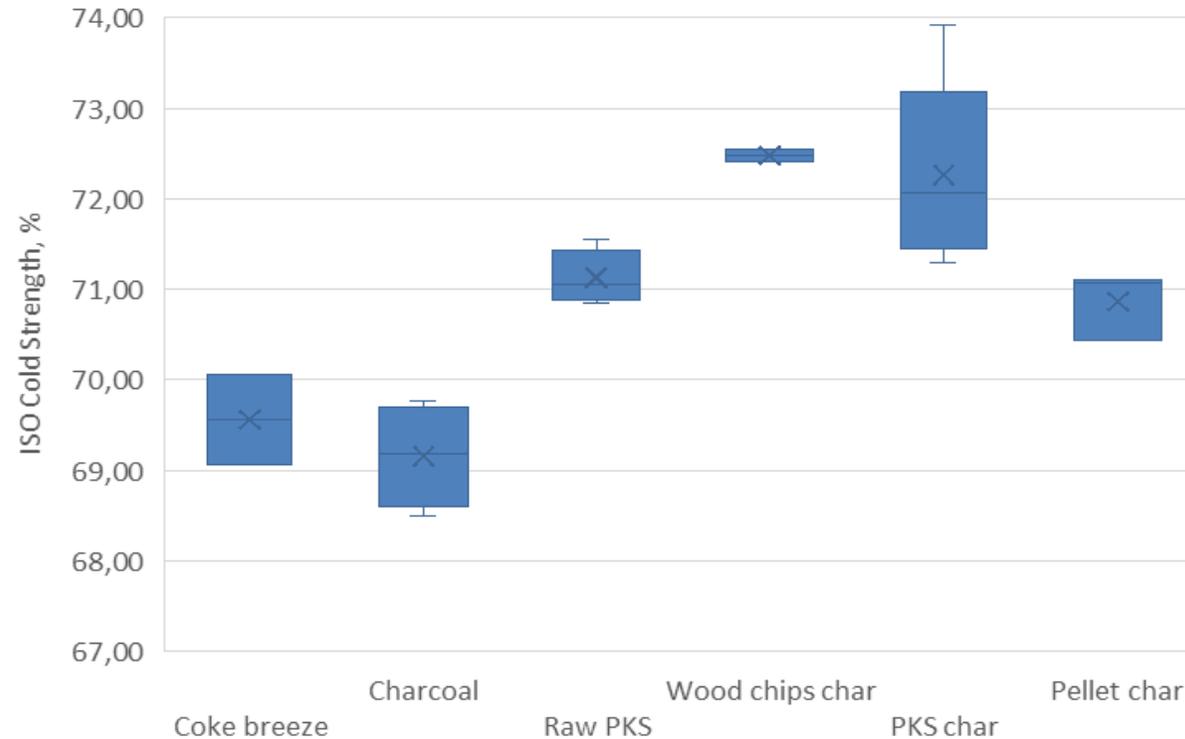

Pellet char improves cold strength up to a 35% substitution level

# Results about biochar application in sintering process

## ISO T COLD STRENGTH

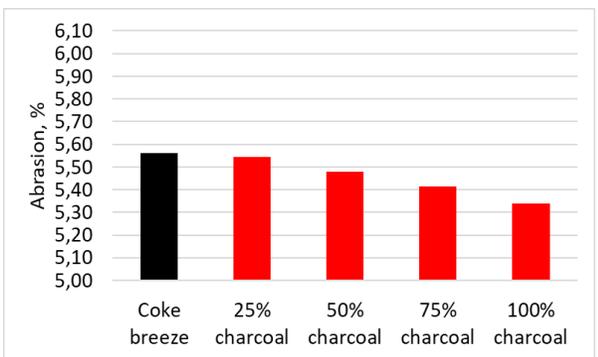

The ISO cold strength improves with all alternative fuels compared to coke breeze, with wood-chips char and PKS char showing the highest values, while charcoal and pellet char provide moderate yet still enhanced strength

# Results about biochar application in sintering process

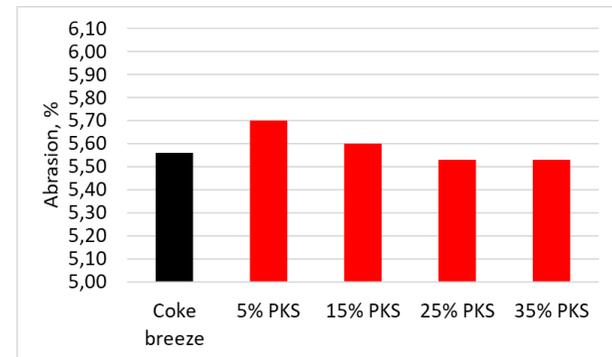

## ISO A ABRASION

### Charcoal

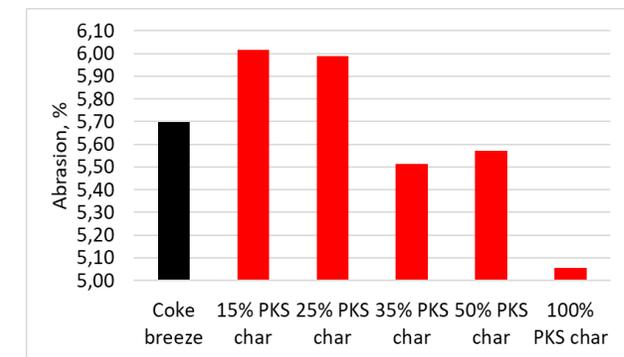

Increasing charcoal substitution reduces abrasion, yielding values lower than those of coke breeze

### Raw PKS

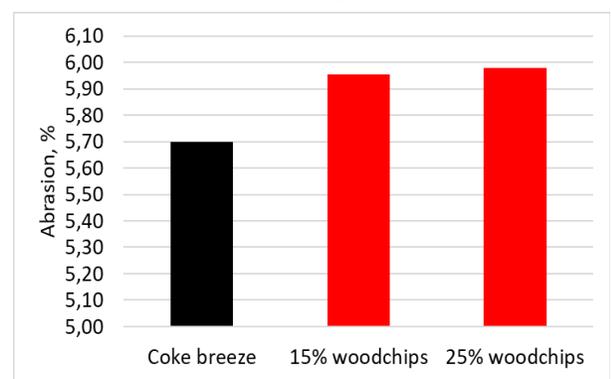

At 15% raw PKS substitution, abrasion exceeds that of coke breeze, whereas at 25% and 35% it falls below the coke-breeze reference

### PKS char

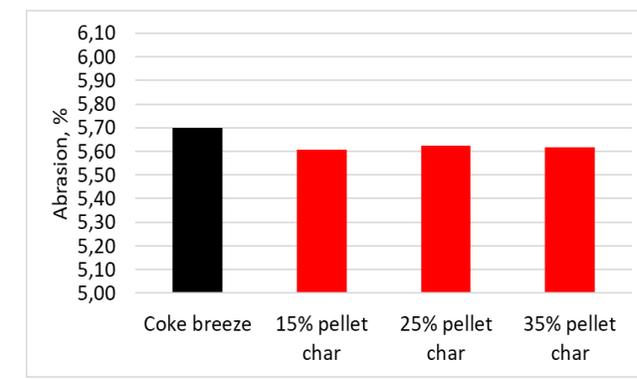

PKS char increases abrasion up to a 25% substitution level, but at 35% the abrasion becomes lower than for coke breeze

### Wood chips char

Wood-chips char substitution initially results in abrasion values higher than those of coke breeze

### Pellet char

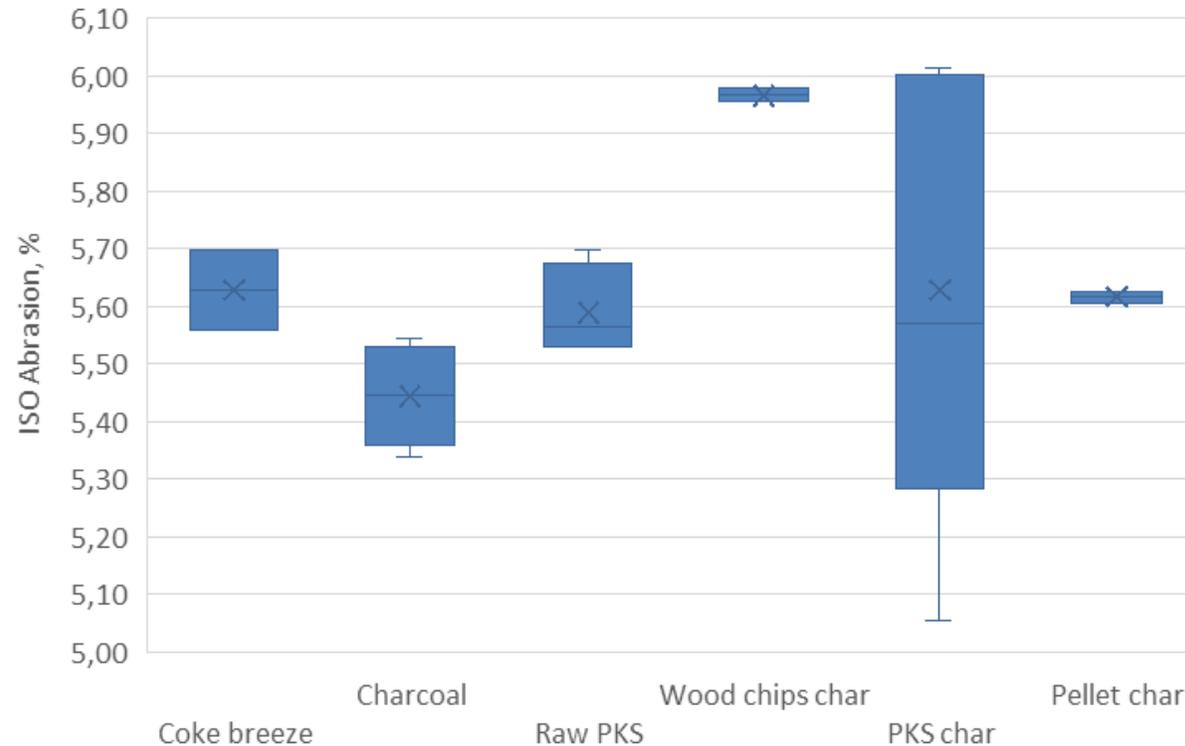

Pellet char produces abrasion values lower than those of coke breeze

# Results about biochar application in sintering process

## ISO A ABRASION

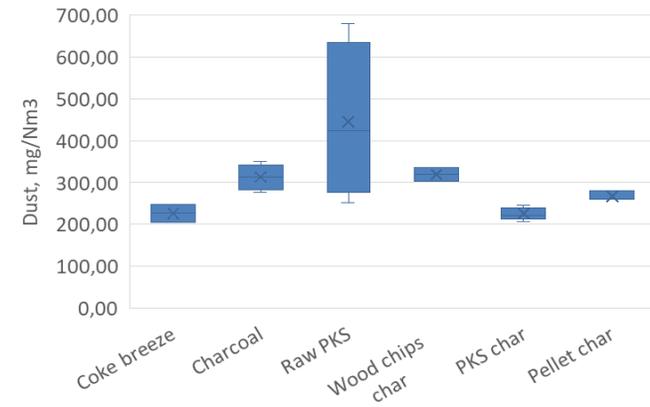

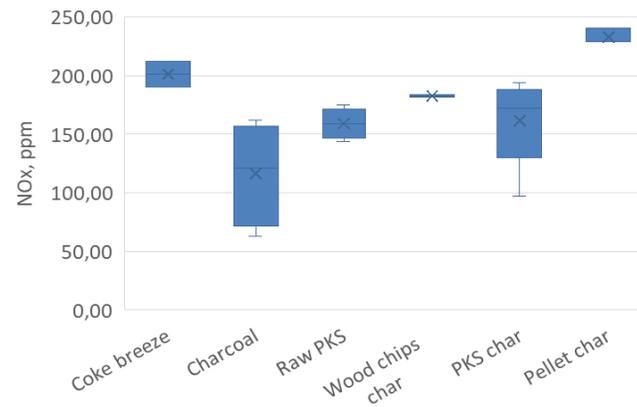

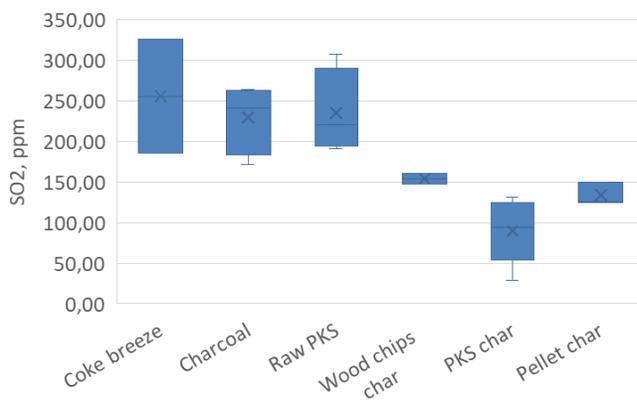

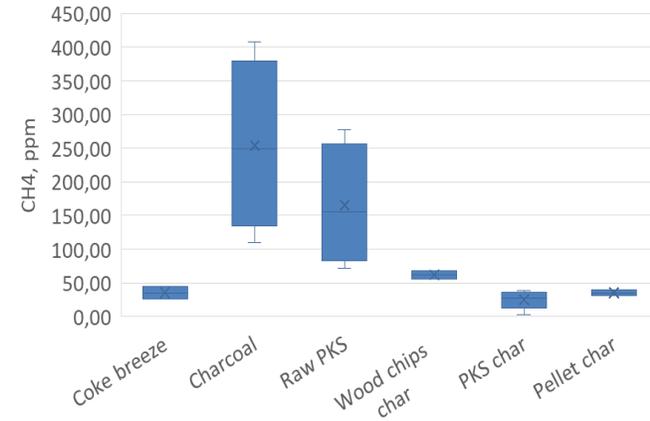

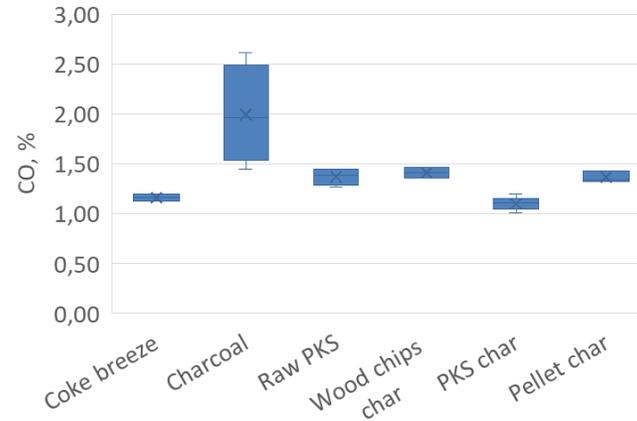

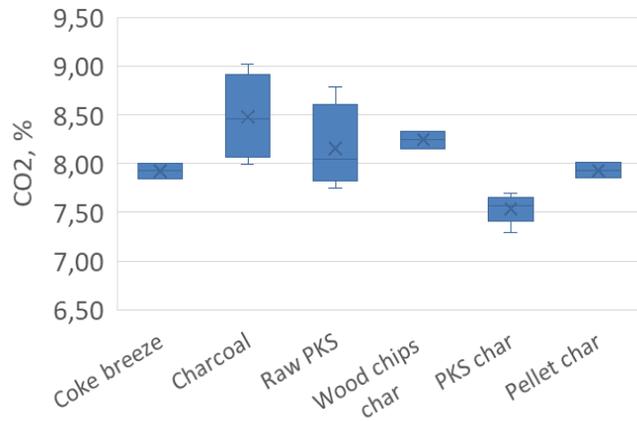

Abrasion varies across the alternative fuels: charcoal shows the lowest abrasion, comparable to or better than coke breeze, while raw PKS and wood-chips char exhibit slightly higher values. PKS char demonstrates the highest abrasion variability, whereas pellet char remains close to the coke-breeze baseline.

# Results about biochar application in sintering process

## CONTENT IN OFF GASES Before gas cleaning system

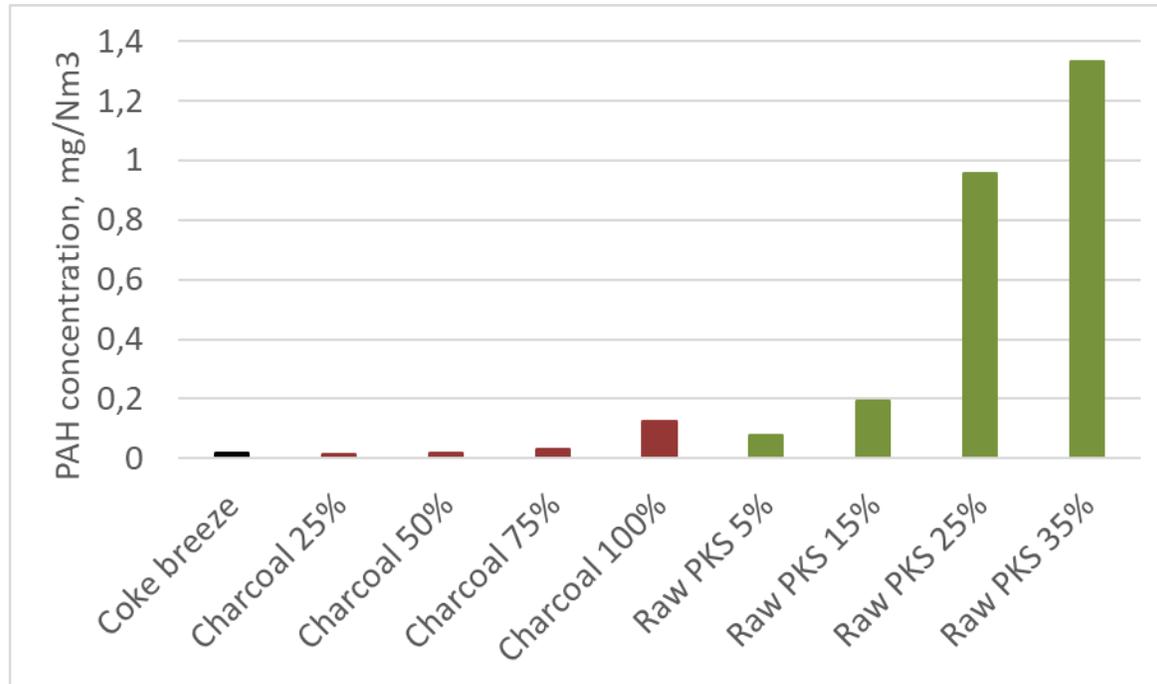

Across all measured pollutants, charcoal and raw PKS generate higher CO<sub>2</sub>, CO, CH<sub>4</sub>, and dust emissions than coke breeze, whereas PKS char and pellet char consistently produce the lowest levels of gaseous and particulate pollutants. SO<sub>2</sub> and NO<sub>x</sub> emissions decrease for most biomass-derived fuels, indicating cleaner sulfur and nitrogen combustion pathways, with the exception of moderate NO<sub>x</sub> increases observed for some materials.

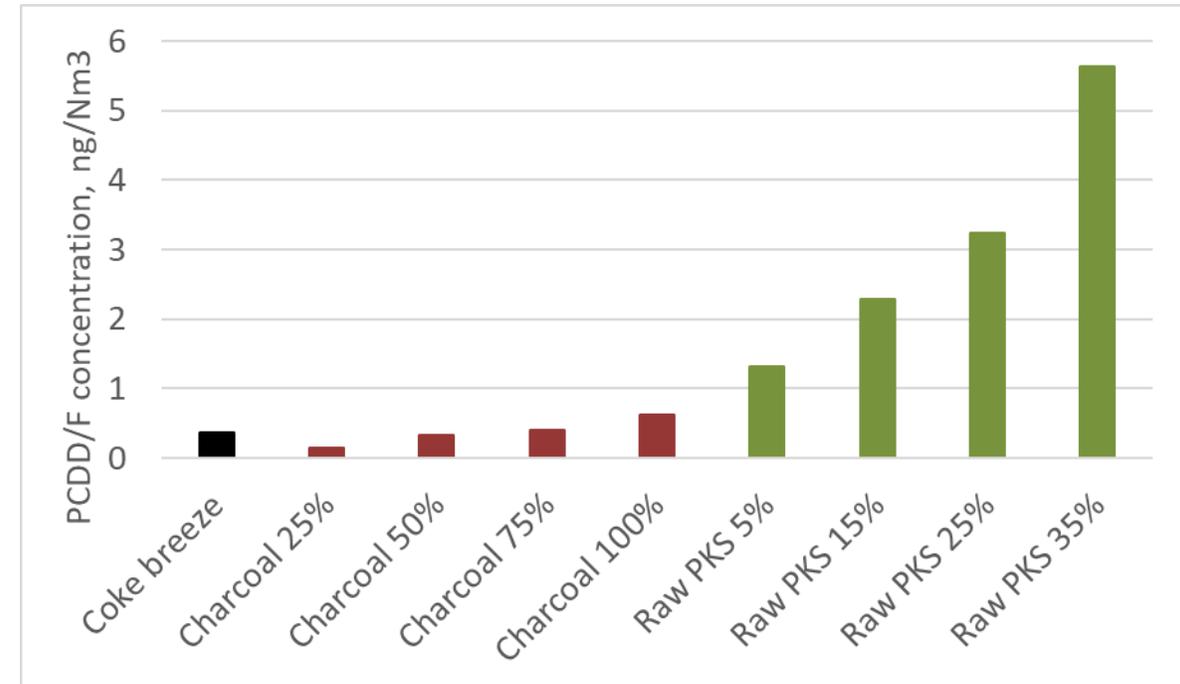

# Results about biochar application in sintering process

## CONTENT IN OFF GASES Before gas cleaning system

PAH emissions remain low and comparable to coke breeze for all charcoal substitution levels, whereas raw PKS shows a strong increase in PAH concentration at higher replacement ratios, indicating that untreated biomass significantly enhances PAH formation.

PCDD/F emissions stay at low levels for charcoal-based substitution, while raw PKS leads to a substantial rise in dioxin and furan concentrations with increasing replacement ratios.

PAH and PCDD/F analyses for the rest of the alternative fuels are in progress

# Results about biochar application in sintering process

## CONCLUSIONS

- **Productivity:** Charcoal and both raw and charred PKS show the highest productivity ( $\approx 40$  t/m<sup>2</sup>/day), outperforming coke breeze; pellet char is slightly lower but still better, while wood-chip char performs worse.
- **Solid fuel consumption:** Raw PKS and charcoal increase consumption due to lower carbon content, whereas PKS char and pellet char reduce it.
- **Mechanical behaviour:** Charcoal, raw PKS, PKS char, and wood-chip char generally improve ISO T, while pellet char enhances cold strength at moderate substitution. Abrasion trends are material-dependent: charcoal reduces abrasion, raw PKS and PKS char shift from higher to lower abrasion with increased substitution, and wood-chip char shows inconsistent effects.
- **Gaseous emissions:** Charcoal and raw PKS increase CO<sub>2</sub>, CO, and CH<sub>4</sub>, whereas PKS char and pellet char substantially reduce gaseous pollutants. SO<sub>2</sub> and NO<sub>x</sub> typically decrease with biomass fuels; pellet char yields the lowest dust emissions.
- **Toxic organic emissions:** PAH and PCDD/F remain low for charcoal but rise sharply with higher raw PKS substitution, showing strong fuel-type dependence.

**There is a possibility of fully (100%) substituting coke breeze with charcoal and PKS char, with the PKS char exhibiting the most beneficial effect on process productivity, fuel consumption, sinter strength, and emissions.**

## METHODOLOGY

### X-Ray diffraction

Qualitative phase analysis

Quantitative phase analysis –  
Rietveld's method

### Scanning Electron Microscopy

Microstructure observation

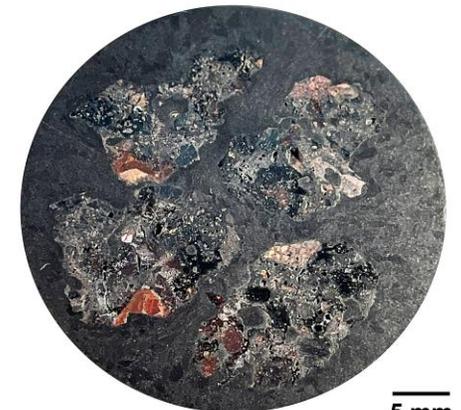

Chemical analysis in  
micro-areas

Samples of sinters for diffraction tests were crushed to a grain size of less than 10  $\mu\text{m}$ .

The sample for quantitative phase analysis was prepared as a mixture of a known amount of sample supplied and powdered corundum.

For microscopic examination the sinter grains were embedded in a conductive resin without crushed.

5 mm

# Results about biochar application in sintering process

An amorphous component in a sintered material is a phase that does not have a regular, crystalline

## Significance of the amorphous component

### Positive effects

Increases density and tightness of the sinter

Improves chemical resistance

Acts as a binding phase between crystalline grains

Can enhance sinterability (lowers sintering temp)

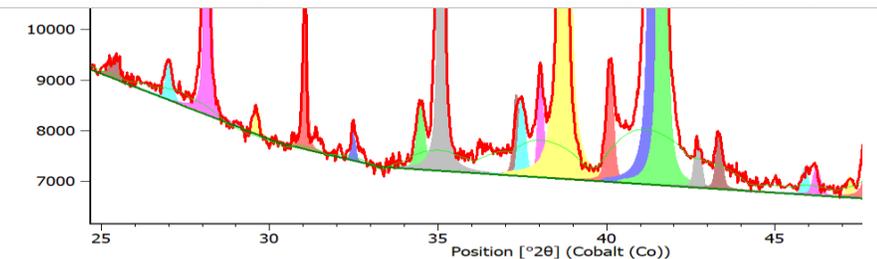

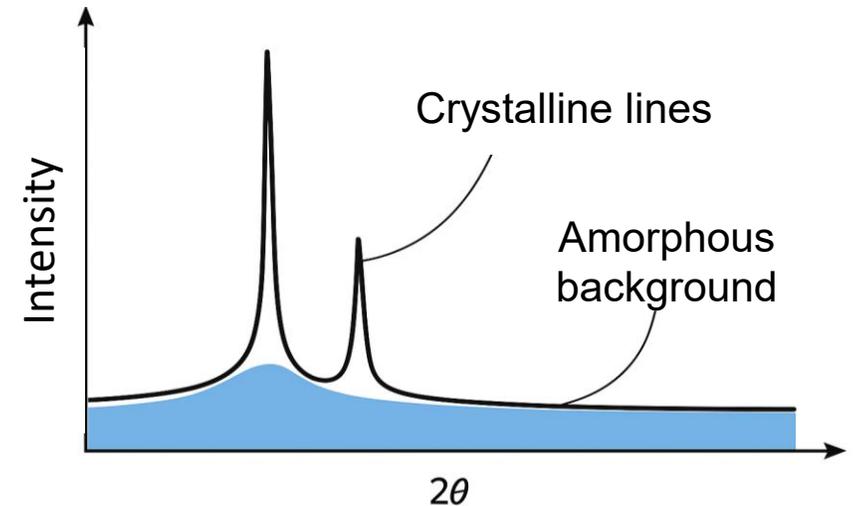

### Negative effects

May reduce hardness or strength at high temperatures

Is often less thermally stable

Can cause creep or deformation during long-term exposure

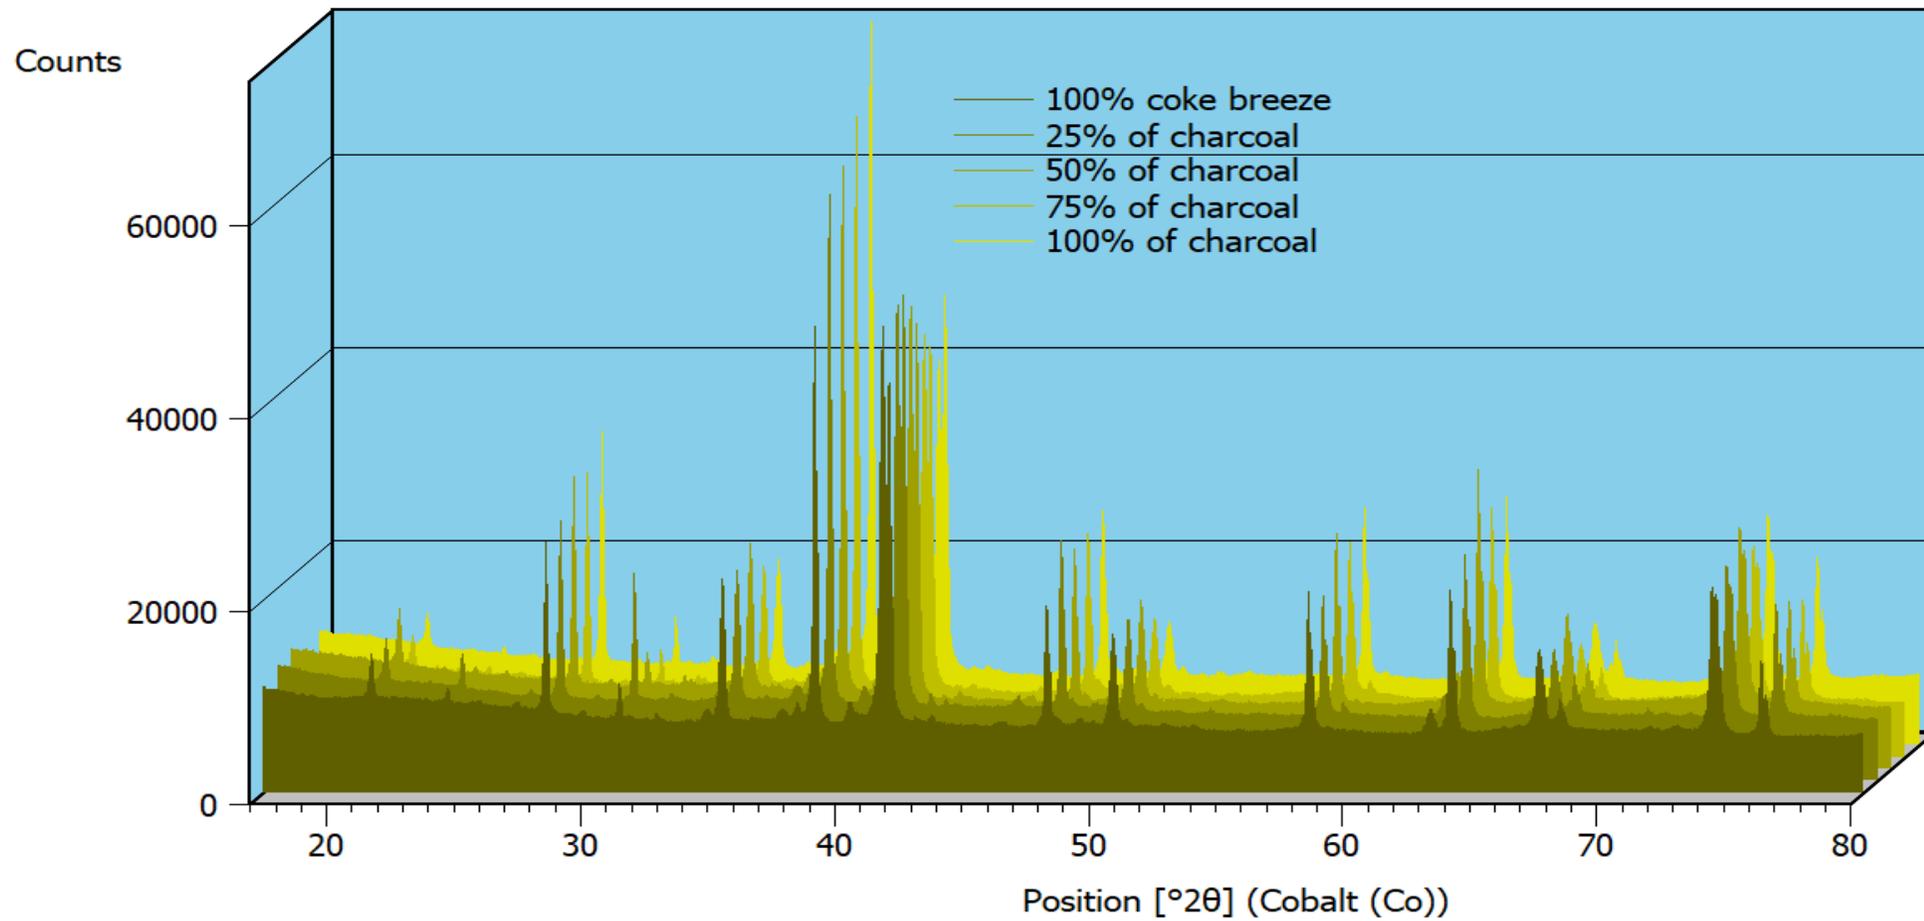

$$X_{amorph} = 100\% - X_{cryst}$$

## Conclusions

Regardless of the biomass added, sinters are characterized by similar, complex phase compositions. Differences occur in the content of individual phases within the sinter.

Adding biomass to the coke breeze significantly increases the proportion of hematite  $\text{Fe}_2\text{O}_3$  and magnetite  $\text{Fe}_3\text{O}_4$  in the sinters. A decrease in the magnesioferrite  $\text{MgFe}_2\text{O}_4$  content is observed. The wüstite  $\text{FeO}$  content remains unchanged.

The total content of silicate phases ranges from 15 to 19%. The highest content of 19% occurs for sinter with 25% Raw palm kernel shell (PKS).

The presence of a silicate phase, rankinite, was observed in the sinters containing 100% Coke Breeze and charcoal, with the exception of the sinter containing 25% charcoal. In the PKS sinters, diopside, which is formed by the decomposition of rankinite under high temperature, was observed. This suggests that a greater amount of heat was delivered to the sinters during the sintering process than in the case of sinters containing charcoal.
